Thinking

**Control theory** classical control theory、 modern control theory、 intelligent control theory

**Classical control** applying the time domain method, the root locus method and the frequency domain method to design controller for a plant

**Modern control** linear system theory、 optimal control theory and optimal estimation theory, etc.

**intelligent control** neural network, expert system and artificial intelligence

The basis of modern control, mainly to solve the model description and basic knowledge of the system. That is, a linear system can generally be described as:

$$\dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{u} \quad (1)$$

$$\mathbf{y} = \mathbf{C}\mathbf{x} + \mathbf{D}\mathbf{u} \quad (2)$$

**Optimal Control** Solve how to obtain the optimal input  $\mathbf{u}(t)$  under the constraint of a certain performance criteria;

**Optimal estimation** Mainly solve the estimation and prediction of the state variable  $\mathbf{X}$

Thinking

- Prerequisites for solving the above problem:
  - A, B, C, and D in the model are known.
  - That is, the structure and parameters of the system are known.
  - That is to know the transfer function of the system, or the impulse transfer function, or the difference equation, or the frequency characteristics of the system.
- So how do you get the structure and parameters of the system?
- System identification purpose: How to get the model of the system and its parameters?

**Model definition** Part of the essence of the system is reduced to a useful form of description.

**Model characteristics**

- Multiple model descriptions can be used for the same system;
- The same model can reflect different actual systems;
- Model accuracy and complexity。

- intuition model
- physical model
- chart model
- mathematical model.

Among them, the chart model is a non-parametric model, and the mathematical model is a parametric model.

Error Criteria

Thinking

system identification acquires the non-parametric model and parametric model of a system.

**non-parametric model**     • frequency characteristic curve

- impulse response curve

**parametric model**     • differential/difference equation

- transfer function
- impulse transfer function

**model conversion**     • The parametric models can be transformed from each other;  
• The non-parametric model can be transformed into a parametric model.

Thinking

- theoretical analysis method
- experimental test method: use the system input and output data to establish a mathematical model of the system.

- The purpose of the model is definite;
- clear physical concept;
- identification is unbiased and consistent;
- conforms to the law of parsimony (Occam's razor).  
The number of parameters to be identified is small.

- Definition: Based on the system input and output data, determine a model equivalent to the system being tested from a given set of model classes.
- Three elements of system identification: data, model classes and criteria.
  - Data: recorded input/output data, often containing noise;
  - Model class: selected models
  - Criterion: This is the cost function, usually the error criterion.

# System Identification General Process

System identification is divided into model structure identification and model parameter identification. The general process is:

- clarifies the purpose of the identified system model;
- pre-select the type of mathematical model of the system to be identified;
- design the experiment for identification, recording I/O data;
- data preprocessing, wild point culling;
- model structure identification, identification system order  $n$ ;
- select the parameter estimation method to identify other parameters of the system;
- model validation.

The focus of this course: parameter estimation method

Thinking

- linear system identification and nonlinear system identification;
- centralized parameter identification and distributed parameter identification;
- system structure identification and system parameter identification;
- classic identification and modern identification;
- open loop system identification and closed loop system identification;
- Offline identification and online identification.

- Process: After the system model and order  $n$  are selected, record all the I/O data of the system, and then use the parameter estimation method to identify the model parameters of the system.
- Features: The amount of data to be stored is large, the amount of calculation is large, and the recognition accuracy is high. Post-mortem data processing methods cannot be used in real-time control systems.

- process: After the system model and order  $n$  are selected, first obtain a small amount of data, estimate the system model parameters, and then obtain new I/O data, and use the recursive correction algorithm to obtain new parameter estimates, and repeat the above process. Until the system stops running.
- Features: Small amount of data, small amount of calculation, and slightly lower recognition accuracy. It is an online data processing method for real-time control systems.

Error criteria are usually expressed as functionalities of errors

$$J(\theta) = \sum_{k=1}^N f(\epsilon(k)) \quad (3)$$

$\epsilon(k)$  is the error between the model and the actual system. It can be output error or input error, or it can be generalized error. The general function  $f$  is taken as the square of the error:

$$f(\epsilon(k)) = \epsilon^2(k) \quad (4)$$

- Input error  $\epsilon(k) = u(k) - u_m(k) = u(k) - S^{-1}[y_m(k)]$
- output error  $\epsilon(k) = y(k) - y_m(k)$

This course uses output errors.
